

# Debug Snapshots

After you have deployed or started your app, you can open Cloud Debugger in the Google Cloud Console. Debugger allows you to capture and inspect the call stack and local variables in your app without stopping or slowing it down.

Visit the [Debug](https://console.cloud.google.com/debug) (<https://console.cloud.google.com/debug>) page of the Cloud Console to use Debugger.

## Before you begin

Debugger can be used with or without access to your app's source code. If your source code isn't available, see [Take a debug snapshot \(#take\\_a\\_debug\\_snapshot\)](#) below for instructions on entering the file name and line number manually.

To access source code that's stored locally or in a Git repository, you may need to [select a source code location](#) ([/debugger/docs/source\\_options](/debugger/docs/source_options)).

## Snapshots

Snapshots capture local variables and the call stack at a specific line location in your app's source code. You can specify certain conditions and locations to return a snapshot of your app's data, and view it in detail to debug your app.

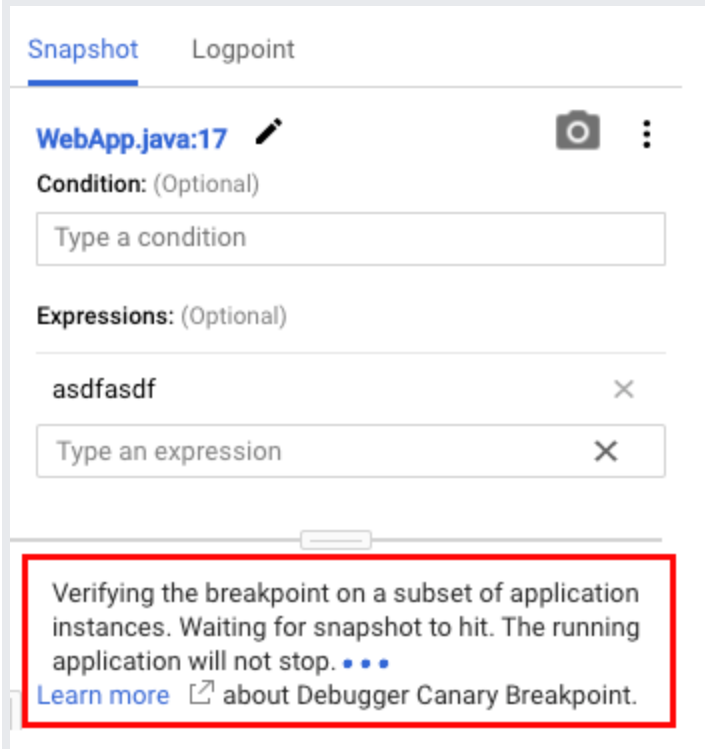

## Debugger agent with canarying

After you set a snapshot, the Debugger agent tests the snapshot on a subset of your instances. After the Debugger agent verifies the snapshot can execute successfully, the snapshot is applied to all your instances. This takes about 40 seconds.

After this process, when the snapshot is triggered, the results appear in the **Variables** and **Call Stack** panes. If the snapshot is triggered within 40 seconds after setting it, you see the results from those instances that had the canary snapshot applied to it.

The Debugger agent implements several strategies for minimizing the amount of latency caused when capturing the data.

You see the following while the Debugger agent is canarying:

To learn what to do if the Debugger agent fails while in canary mode, go to the [Troubleshooting section on the Debug snapshots page](/debugger/docs/using/snapshots#troubleshooting) (/debugger/docs/using/snapshots#troubleshooting).

To learn what Debugger agent versions have canary functionality, see the language-specific pages.

## Debugger agent without canarying

When you use the Debugger agent without canarying and set a snapshot, it applies to all running instances of your app. The first time any instance executes the code at the snapshot location, the Debugger agent takes a snapshot and makes it available for viewing. The Debugger agent implements several strategies for minimizing the amount of latency caused when capturing the data.

A snapshot is only taken *once* during app runtime. You can manually [retake the snapshot](#) (#retake\_a\_snapshot) to capture a new set of data.

snapshots might not be available during startup, while the Debugger agent initializes in the background.

## Take a debug snapshot

### Consolegcloud (#gcloud)

Click the source code line number to take a snapshot at that location.

1. Make sure that the **Snapshot** panel is selected in the right panel.
2. In the left panel, select the file that contains the source code to watch. The contents of the selected file are displayed in the center panel.
3. Click the line number of the source code location.

The screenshot displays the Google Cloud Platform Cloud Debugger interface. At the top, the navigation bar includes the Google Cloud Platform logo and the application name 'cloud-debugger-demo'. Below this, the 'Stackdriver Debug' section is active, showing the current environment as 'default - v1 (100%)'. The main interface is divided into three panels. The left panel shows a file explorer with the following structure:

- cloud repository:/
  - src/main
    - java/com/google/cloud/debugger/mandelbrot
      - FractalCalculator.java
      - GeneratorServlet.java**
      - ImageGenerator.java
    - webapp
    - .gitignore
    - deploy.sh
    - pom.xml

The center panel displays the source code for 'GeneratorServlet.java'. The code is as follows:

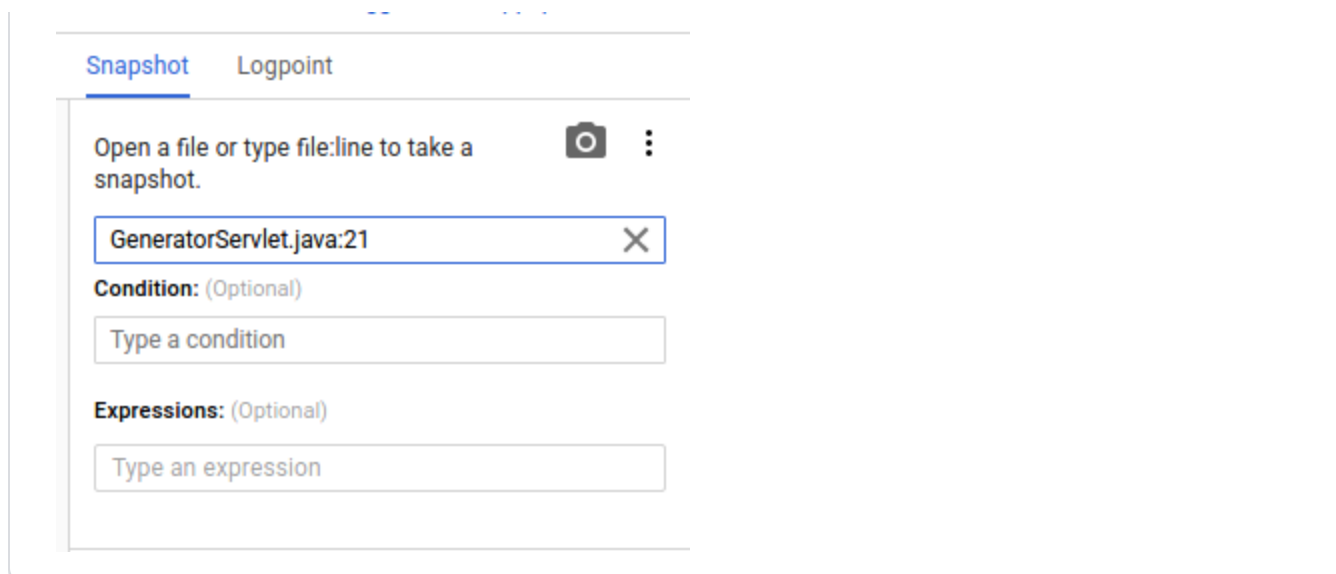

```
14
15 @Override
16 public void doGet(HttpServletRequest req, Ht
17 // Set the MIME type of the image.
18 resp.setContentType("image/png");
19
20 // Disable cache.
21 resp.setHeader("Cache-Control", "no-cache,
22 resp.setDateHeader("Expires", 0);
23
24 FractalCalculator calculator = new Fractal
25
26 final int imageSize = 305;
27
```

A mouse cursor is clicking on line number 21 in the code editor.

You can click multiple lines to set more than one snapshot location on a file.

See the [Source code options](#) (#source\_code\_options) section for other ways to load your source code in Debugger.

If no source code is available, you can manually enter the filename:line to take a snapshot in the **Snapshot** panel:

## Snapshot conditions (optional)

A snapshot condition is a simple expression in the app's language (Java, Python, and Go are supported) that must evaluate to true for the snapshot to be taken. Snapshot conditions are evaluated each time the line is executed, by any instance, until the condition evaluates to true or the snapshot times out.

Use of snapshot conditions is optional.

The condition is a full boolean expression that can include logical operators:

```
lAccessory == "Towel"  
ateAnswer <= 42  
lAccessory == "Towel" && ultimateAnswer <= 42
```

### Consolegcloud (#gcloud)

To specify the condition, enter it in the **Condition** field in the **Snapshot** panel.

Snapshot
Logpoint

```

27
28     try {
29         BufferedImage bufferedImage =
30             new BufferedImage(imageSize, ima
31
32         long startTime = System.nanoTime();
33
34         float cxminFrame = -2;
35         float cyminFrame = -1.5f;
36         float frameLength = 3;
37
38         float scale = randomRange(0.7f, 1);
39         float cxCenter = randomRange(cxminFr
40         float cyCenter = randomRange(cyminFr
41
42         float cxmin = cxCenter - scale * fra
43         float cxmax = cxCenter + scale * fra
44         float cymin = cyCenter - scale * fra
45         float cymax = cyCenter + scale * fra
46
47         // Compute points
48         float[][] iterationMap = new float[i
49         for (int y = 0; y < imageSize; ++y)
50             for (int x = 0; x < imageSize; ++x
51                 float cx = cxmin + (cxmax - cxmi

```

**GeneratorServlet.java:39**

Condition: (Optional)

✕

Expressions: (Optional)

**Variables** 2017-05-02 (12:16:36)

- ▶ this
- ▶ req
- ▶ resp
- ▶ bufferedImage
- startTime 5088001243072327
- cxminFrame -2
- cyminFrame -1.5
- frameLength 3
- scale 0.989364

You can use the following language features to express conditions:

### [Java](#)[Python](#) (#python)[Go](#) (#go)

Most Java expressions are supported, including:

- Local variables: `a == 8`.
- Numerical and boolean operations: `x + y < 20`.
- Instance and static fields: `this.counter == 20`, `this.myObj.isShutdown`, `myStatic`, or `com.mycompany.MyClass.staticMember`.
- String comparisons with the equality operator: `myString == "abc"`.
- Function calls. Only read-only functions can be used. For example, `StringBuilder.indexOf()` is supported, but `StringBuilder.append()` is not.
- Type casting, with fully qualified types: `((com.myprod.ClassImpl) myInterface).internalField`

The following language features are **not** supported:

- Unboxing of numeric types, such as `Integer`; use `myInteger.value` instead.

## Expressions (optional)

Debugger's Expressions feature allows you to evaluate complex expressions or traverse object hierarchies when a snapshot is taken. Expressions support the same language features as [snapshot conditions](#) (`#snapshot_conditions`), described above.

Use of expressions is optional.

Typical uses for expressions are:

- To view static or global variables that are not part of the local variable set.
- To easily view deeply nested member variables without having to expand a local variable in the Debugger panel every time.
- To avoid repetitive mathematical calculations. For example, calculating a duration in seconds with `(endTimeMillis - startTimeMillis) / 1000.0`.

To add an expression:

### [Consolegcloud](#) (#gcloud)

1. Enter the expression in the **Expression** field. Press the tab key to add additional expressions.
2. Press the Enter key or the **Snapshot** button

The result of the expression is shown when the snapshot is taken.

## View a snapshot

### [Consolegcloud](#) (#gcloud)

Snapshot data appears in Debugger when the app executes the source code at the location you specified. Instance variables and local variables appear in the **Variables** section of the panel. The stack trace appears in the **Call Stack** section of the panel.

The screenshot shows the Google Cloud Platform Cloud Debugger interface. The top navigation bar includes the Google Cloud Platform logo, the application name 'cloud-debugger-demo', and various utility icons. Below the navigation bar, the application is identified as 'Stackdriver Debug' with a version of 'default - v1 (100%)'. The main area is divided into two panels: 'Source' and 'Snapshot/Logpoint'. The 'Source' panel shows the code for 'GeneratorServlet.java', with line 22 highlighted. The 'Snapshot' panel shows the details of a snapshot taken at 2017-05-02 (12:27:31). It includes fields for 'Condition' (Optional), 'Expressions' (Optional), and 'Variables'. The 'Variables' section shows a tree view of the current object, including 'this', 'config', 'this\$0', '\_listeners', and '\_lock'. The 'Call Stack' section shows the current method 'GeneratorServlet.java:22' and the caller 'HttpServlet.java:618'.

You can examine the value of local variables at the moment the snapshot was taken, and drill down into deeper data structures. You can also click on any call stack frame, and examine the local variables at that level in the stack.

If you've set multiple snapshot locations on a file, or to view snapshots that you've already taken, expand the **Snapshot History** panel:

The screenshot shows the 'Snapshot History' panel in the Cloud Debugger interface. The panel is titled 'Showing 2 snapshots' and has a search filter 'Filter by file, condition, expressions, or user'. Below the filter, there are two snapshot entries for 'GeneratorServlet.java:26':
 

- One entry is 'Waiting for snapshot to hit...' with a blue icon.
- Another entry is 'Captured at 2017-05-02 (12:27:31)' with a grey icon.

 The source code for 'GeneratorServlet.java' is visible in the background, with line 26 highlighted.

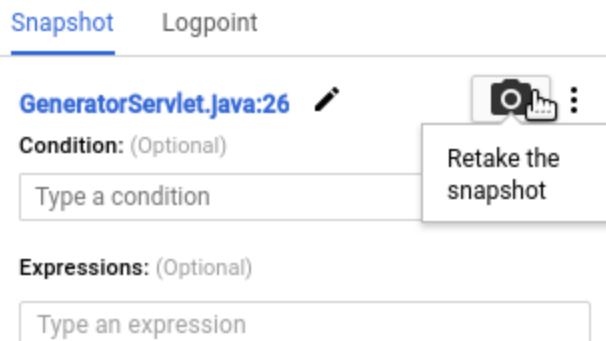

## Retake a snapshot

A snapshot is only taken once. If you want to capture another snapshot of your app's data at the same location, you can manually retake it.

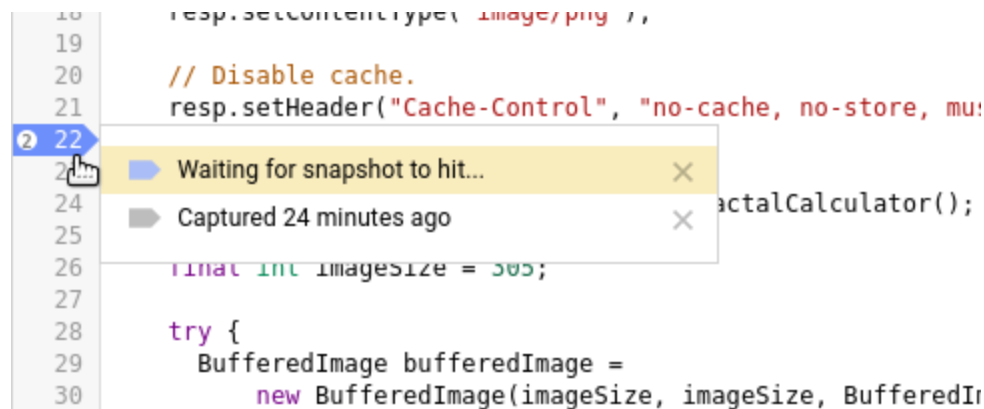

## Consolegcloud (#gcloud)

To retake a snapshot, click the camera icon at the top-right of the **Snapshot** panel:

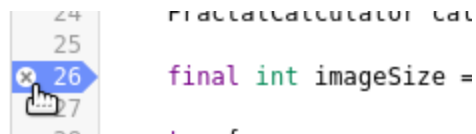

The new snapshot is added to the **Snapshot History** panel. Past snapshots on that line can be accessed from the **Snapshot History** or from the marker on that line number:

## Remove a snapshot location

### Consolegcloud (#gcloud)

Remove a snapshot location by clicking the X in the snapshot marker.

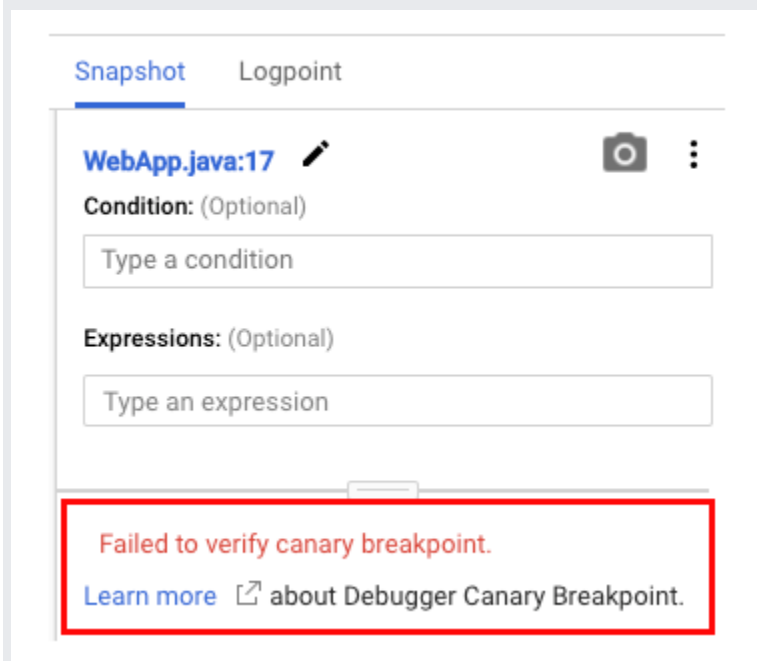

## Share snapshots

You can share a snapshot with another project member by copying the snapshot URL from your browser or from the output of the `gcloud debug snapshots list` (`/sdk/gcloud/reference/debug/snapshots/list`) command and giving it to another user who has access to your project. You can also save this URL for future reference and come back to it again to view its results. Debugger uses a new URL for each snapshot taken. This allows you to share distinct sets of results even if they were captured at the same location in the code. Sharing expires 30 days after the snapshot has been taken.

## Troubleshooting

### Has the Debugger agent crashed my instances?

You might see the following error if the Debugger agent is faulty:

You could get false-positives that make it appear as if the Debugger agent has triggered its safeguards for the following reasons:

- An instance was shut down while the Debugger agent was canarying.

When an instance that has a canary snapshot applied to it is shut down, it appears like the Debugger agent terminated the instance. Verify no instances were shut down within 40 seconds after the snapshot was set. For example, autoscaling from Cloud Run and App Engine, or deploying new code could be reasons instances are shut down.

You should remove the Debugger agent from your instances and reinstall the previous version. To reinstall the previous version, follow the setup instructions for [installing the previous version of the Debugger agent](#) (/debugger/docs/setup).

If the issue persists with the old version of the agent, verify that it isn't a false-positive, then disable the Debugger agent and send feedback.
